Running title: Galanin(1-15) enhances Fluoxetine effect

Abstract

The pharmacological treatment of major depression is mainly based on drugs elevating serotonergic (5-HT) activity. Specifically, selective 5-HT reuptake inhibitors, including Fluoxetine (FLX), are **the most commonly used** for treatment of major depression. However, the understanding of the mechanism of action of FLX beyond its effect of elevating 5-HT is limited. The interaction between serotonergic system and neuropeptides signalling could be a key aspect. We examined the ability of the neuropeptide Galanin(1-15) [GAL(1–15)] to modulate the behavioral effects of FLX in the forced swimming test (FST) and studied feasible molecular mechanisms. The data show that GAL(1-15) enhances the antidepressant-like effects induced by FLX in the FST, and we demonstrate the involvement of GALR1/GALR2 heteroreceptor complex in the GAL(1-15)-mediated effect using *in vivo* rat models for siRNA GALR1 or GALR2 knockdown.

Importantly, 5-HT_{1A} receptors (5HT_{1A}R) also participate in the GAL(1-15)/FLX interactions since the 5HT_{1A}R antagonist WAY100635 blocked the behavioral effects in the FST induced by the coadministration of GAL(1-15) and FLX. The mechanism underlying GAL(1-15)/FLX interactions affected the binding characteristics as well as the mRNA levels of 5-HT_{1A}R specifically in the dorsal hippocampus while leaving unaffected mRNA levels and affinity and binding sites of this receptor in the dorsal raphe. The results open up the possibility to use GAL(1-15) as for a combination therapy with FLX as a novel strategy for treatment of depression.

INTRODUCTION

Major Depression is the most frequent mood disorder, with a lifetime prevalence that has been reported to range from 7% to 21% (Albert et al., 2011). It is associated with a substantial functional impairment, diminished quality of life, increased burden both for patients and caregivers, as well as with a higher risk of mortality.

Although several neurotransmitter systems and brain areas have been implicated in this pathology, the pharmacological treatment of major depression is mainly based on drugs elevating serotonergic (5-HT) activity (Blier and de Montigny, 1994; Jans et al., 2007). Specifically, selective 5-HT reuptake inhibitors (SRRIs) are **the most commonly used** for treatment of major depression. In particular, Fluoxetine (FLX) is usually chosen for the treatment of symptoms of depression (Artigas, 2013). However the understanding of the mechanism of action of FLX beyond its effect of elevating 5-HT is limited. Recent studies have also implicated several neuropeptides in the pathophysiology of depression **in rodents** and in the possibility to use them as a combined treatment with antidepressant drugs.

In this context, the neuropeptide Galanin (GAL) (Tatemoto et al., 1983) is of particular interest. GAL is widely distributed in neurons within the Central Nervous System (CNS) and three GAL receptor (GALR) subtypes, GALR1-3 with a high affinity for GAL have been cloned (Branchek et al., 2000; Mitsukawa et al., 2008). GALR1 and GALR3 mainly activate inhibitory G proteins Gi/Go, while GALR2 mainly couples to Gq/G11 to mediate excitatory signaling (Branchek et al., 2000; Wang et al., 1997).

GAL participates in mood regulation and depression **in rodents** (Bellido et al., 2002; Juhasz et al., 2014; Wang et al., 2016; Weiss et al., 1998). Thus, the activation of GALR1 and GALR3 results in a depression like behavior while stimulation of GALR2 leads to anti-depressant-like effects (Bartfai et al., 2004; Kuteeva et al., 2008; Lu et al., 2005). **Recently, it has been described that GAL and its receptor GALR3 are differentially methylated and expressed in brains of major depression subjects in a region- and sex-specific manner (Barde et al., 2016).**

In this context, GAL modulates 5-HT_{1A} receptor (5-HT_{1AR}) function at autoreceptor and postsynaptic level in the brain. **In the dorsal raphe (DR), intracerebroventricular (icv) GAL induced a time-dependent reduction in affinity and an increase in the 5-HT_{1AR} autoreceptor density**(Razani et al., 2001). **At the post-synaptic level, GAL reduced the affinity of the 5-HT_{1AR} in the ventral limbic cortex (Fuxe et al., 1988; Hedlund and Fuxe, 1996). Moreover, in hypothermia, locomotor activity and passive avoidance, icv GAL blocked post-synaptic 5-HT_{1AR} function (Kehr et al., 2002; Misane et al., 1998; Razani et al., 2001).** The antagonistic GALR-5-HT_{1AR} interactions described in the brain, especially in the limbic forebrain regions and in the dorsal raphe, has been suggested to be of high relevance for depression (Fuxe et al., 1988; Hedlund and Fuxe, 1996; Kehr et al., 2002; Misane et al., 1998; Razani et al., 2001).

Not only GAL but also the N-terminal fragments like GAL(1-15) are active in the CNS (Diaz-Cabiale et al., 2007; Diaz-Cabiale et al., 2010; Diaz-Cabiale et al., 2005; Hedlund and Fuxe, 1996). Recently we described that GAL(1-15) induces strong depression-related and anxiogenic-like effects in rats and these effects were significantly stronger than the ones induced by GAL (Millon et al., 2015). The GALR1-GALR2 heteroreceptor complexes in the dorsal hippocampus and DR, areas rich in GAL(1-15) binding sites (Hedlund et al., 1992) were involved in these effects (Millon et al., 2015) and demonstrated also in cellular models (Borroto-Escuela et al., 2014).

GAL(1–15) is also able to enhance the antidepressant effects induced by the 5-HT_{1AR} agonist 8-OH-DPAT in the forced swimming test (FST) (Millon et al., 2016), effect that was again significantly stronger than the ones induced by GAL. Importantly, the mechanism underlying this action involved interactions at the receptor level in the plasma membrane with changes also at the transcriptional level. Thus, GAL(1–15) affected the binding characteristics as well as the mRNA levels of 5-HT_{1AR} in the dorsal hippocampus and DR (Millon et al., 2016).

In view of these results the purpose of the current study was to assess the ability of GAL(1–15) to modulate the behavioral effects of FLX. We have analyzed the effect of GAL (1–15) on FLX-mediated responses in a behavioral test of depression. We tested the involvement of GALR2 in the GAL (1–15) effect with the selective GALR2 antagonist M871 and using an in vivo rat model for siRNA GALR2 knockdown. The role of the GALR1 in the behavioral actions of GAL(1–15) were analyzed using an in vivo rat model for siRNA GALR1 knockdown. Moreover, to study whether the effects of GAL(1–15) on FLX action were mediated via 5-HT1AR, we have analyzed the effect of the 5-HT1AR antagonist WAY100635 in the GAL(1-15)-mediated effect in the FST. We have also determined the binding characteristics and mRNA levels of 5-HT1AR in the DR and dorsal hippocampus after GAL(1-15)-FLX administration.

MATERIALS AND METHODS

Animals

Male Sprague-Dawley rats obtained from CRIFFA, Barcelona (200-250gr) were maintained under a 12h dark/light cycle in temperature- and humidity-controlled conditions ($22\pm 2^{\circ}\text{C}$, 55–60%). The animals had free access to food pellets and tap water. Behavioural tests were performed during the light phase of the diurnal cycle. All Experimental procedures were approved by the Institutional Animal Ethics Committee of the University of Málaga, Spain.

Detailed descriptions on animal controlled-conditions, surgical preparation, icv injections, forced swim test (FST) and behavioral scores are available in Supplemental Information.

Forced Swimming Test

Previously to the test, the animals were adapted to experimental room and handled. All tests were performed between 13:00h and 16:00h during the light cycle. Two swimming sessions were conducted: a 15 min pre-test followed 24 h later by a 5 min test. Animals were individually placed in a vertical glass cylinder of 20 cm diameter containing water (25°C) to a height of 30 cm. (Detke and Lucki 1996; Kuteeva et al. 2007). The total duration of immobility, climbing and

swimming behavior were recorded during the second 5 min test. The administration of drugs was performed between sessions.

siRNA GALR1 and GALR2 Knockdown Rats.

Knockdown rats were generated as previously described (Millon et al., 2015). **Using real time quantitative PCR, we have previously performed a time course of GALR2 mRNA in dorsal hippocampus (Millon et al., 2015) and we had also performed a time course of GALR2 protein expression using quantification of immunohistochemical staining for GALR2 in hippocampus (Millon et al., 2015). The time course curve indicated a maximal reduction of GALR2 receptor protein expression 8 days after the injection (Millon et al., 2015).**

Briefly, during the stereotaxic surgery, once the cannula is fixed, animals received an intracerebroventricular (icv) injection of 5 μ g (0.35 nmol) of Accell Smart pool siRNA for GALR2 or GALR1 (Dharmacon). Animals had a recovery period of 8 days prior to behavioural test, the time required to reduce the levels of GAL receptors as previously described (Millon et al., 2015).

Behavioural Assessment

Groups of rats were assessed in the FST. The doses, injection schedule and mode of administration of substances were chosen based on previous work (Estrada-Camarena et al., 2003; Estrada-Camarena et al., 2006; Jorgensen et al., 2001; Millon et al., 2016).

In the first set of experiments, we performed a dose-response curve of FLX. Groups of rats received three injections subcutaneously (sc) of FLX at the doses of 10mg/Kg or 2.5mg/Kg, or vehicle 23, 5 and 1 hour before the tests and an icv injection of artificial cerebrospinal fluid (aCSF) 15 min before the test.

This pattern of injection was shown to produce effects of FLX in the FST similar to those obtained after chronic treatment and to those leading to its clinical effects in humans (Detke et al., 1997). This mode of injection was used in all the experiments of this study.

In the second set of experiments, in order to evaluate the interaction of FLX with GAL(1-15) in the FST, groups of rats received three injections of sc

FLX(2.5mg/Kg) or FLX(10mg/Kg) and a single icv injection of a threshold dose of GAL(1-15)(1nmol) 15 minutes before the test. Also we compared the effects between the coadministration of FLX(10mg/Kg) and GAL(1-15)(1nmol) or GAL(1nmol) in the FST.

In a third set of experiments we determined the involvement of GALR1 and GALR2 in the effect of GAL(1-15) on FLX-mediated action. Groups of rats received three injections of sc FLX(10mg/kg), a single icv injection of GAL(1-15) (1nmol) and the GALR2 antagonist M871 (3nmol) icv alone or in combination. Also, in siRNA GALR1 or GALR2 knockdown rats we coadministered FLX(10mg/Kg) and GAL(1-15)(1nmol) in order to analyze the involvement of GALR1 and GALR2 receptors in the GAL(1-15)-mediated effect.

To further study if the effects of GAL(1-15) on FLX action were mediated via the 5HT1AR, groups of rats received three injections of sc FLX(10mg/kg) **and 15 minutes before the test a single** icv injection of GAL(1-15) (1nmol) and 5HT1AR antagonist WAY100635(6nmol) icv alone or in combination.

Autoradiography and *in situ* hybridization histochemistry

The procedure to perform receptor autoradiography and *in situ* hybridization histochemistry was previously described (Millon et al., 2015; Saenz del Burgo et al., 2013). Rats (n=6 per group) received the three injections of sc FLX or Vehicle and a single icv injection of GAL(1-15) or aCSF, and were sacrificed 30 min later. Coronal sections were obtained at the dorsal hippocampus and DR level (see Supplemental Information for details).

Quantitative autoradiography

Saturation experiments were performed using [³H]-8-OH-DPAT. Briefly, the sections were preincubated for 30 minutes at room temperature in 50mM Tris-HCl buffer (pH 7.6) containing 4mM CaCl₂, 0.01% ascorbic acid and 10mM pargyline. The sections were then incubated for 60 minutes at room temperature with [³H]-8-OH-DPAT in the same solution as above. Film exposure time for sections was 6 weeks (see Supplemental Information for details).

In situ hybridization histochemistry

The oligonucleotides complementary to the mRNA coding for 5-HT_{1A}R are found in Supplemental information. Oligonucleotide labeling, *in situ* hybridization histochemistry and specificity controls have been described elsewhere (Pompeiano et al., 1992; Tomiyama et al., 1997).

Hybridized sections were exposed to Kodak Biomax-MR (Sigma Aldrich) for 10 days.

Image analysis

Measurements were made in the Dentate Gyrus (DG) and the CA1 area of the hippocampus (0.15 mm²). The ventral part of the midline area of the DR was analyzed using a square as a sampling field (0.09mm²) (see Supplemental Information for details).

Statistical Analysis:

Data are presented as the mean±SEM and samples number (n) are indicated in figure legends. All data were analyzed using GraphPad PRISM 4.0 (GraphPad Software, La Jolla, CA). For comparing two experimental conditions, Student's unpaired t-test was performed. Otherwise, one-way analysis of variance (ANOVA) followed by Newman-Keuls comparison post hoc-test was performed. Differences were considered significant at P<0.05 (*P<0.05, **P<0.01, ***P<0.001). The data from the saturation experiments were analyzed by non-linear regression analysis for the determination of the dissociation constant (K_d) and the total number of agonist binding sites (B_{max}) using GraphPad PRISM 4.0.

RESULTS

Behavioral effects

Dose-response to Fluoxetine

As previously described, three injections of FLX given sc at 10mg/Kg induced an antidepressant-like effect in the FST in rats (Table S1). The overall one way

ANOVA revealed a significant effect between treatments in immobility time ($F_{2,20}=4.628$, $p<0.05$) and swimming time ($F_{2,20}=7.044$, $p<0.01$) while no significant difference was observed in climbing time ($F_{2,20}=2.569$, $p=0.102$). FLX(10mg/Kg) reduced the immobility (post hoc, $p<0.05$) and increased swimming time (post hoc, $p<0.01$) compared to controls and FLX 2.5mg/Kg. The three injections of sc FLX 2.5mg/Kg was considered as threshold in this test since it did not produce antidepressant-like effects compared to controls (Table S1).

GAL(1-15) but not GAL enhances antidepressant-like effects of FLX in the FST

The coadministration of the three sc injections of the threshold dose of FLX(2.5mg/Kg) and a single icv injection of GAL(1-15)(1nmol) (Figure S1) induced antidepressant-like effects with a significant decrease in the immobility ($F_{3,27}=3.973$, $p<0.05$) compared with the rest of the groups (Figure S1; post hoc $p<0.05$). Moreover, an increase in the swimming time ($F_{3,28}=4.137$, $p <0.05$) compared with GAL(1-15) and controls was also observed (Figure S1; post hoc, $p<0.05$).

The strong enhancement by GAL(1-15) of the antidepressant-like effects mediated by FLX was validated using the effective dose of FLX 10mg/kg in the FST. The threshold dose of GAL(1-15) 1nmol enhanced the antidepressant-like effects mediated by the three sc injections of FLX(10mg/kg) since the overall one way ANOVA revealed a reduction in the immobility time ($F_{3,28}=10.96$, $p<0.001$) and an increase in the swimming time ($F_{3,28}=16.46$, $p<0.001$) without effects on climbing time ($F_{3,27}=0.7554$, $p=0.5289$) (Fig. 1). Icv GAL(1-15) significantly decreased the immobility time induced by the three injections of the effective dose of FLX (10mg/kg) by 50% in the FST (Figure 1; post hoc $p<0.05$). Moreover, an increase of the swimming time by about 40% versus FLX (10mg/kg) group was also observed ($p<0.01$).

The coadministration of three sc injections of FLX(10mg/Kg) and a single icv injection of GAL(1nmol) lacked effects on the immobility and swimming behaviours compared to FLX (10mg/kg) in the FST (Figure 1).

GAL Receptor subtypes involved in the GAL(1-15)–Fluoxetine interaction

We tested the involvement of the GALR2 in the GAL(1–15)-FLX(10mg/kg) interaction with the selective GALR2 antagonist M871 and using an in vivo rat model of siRNA GALR2 knockdown.

1. Effects of the GALR2 antagonist M871

The GALR2 antagonist M871 3nmol significantly blocked the GAL(1–15)-induced reduction of the immobility time ($F_{3,28}=10.20$, $p<0.001$;post hoc, $p<0.05$), and the GAL(1–15)-induced increase in the swimming time ($F_{3,29}=15.75$, $p<0.001$;post hoc, $p<0.01$) found after coadministration of a single icv injection of GAL(1-15) and the three sc injections of FLX (10mg/kg) in the FST (Figure 2A). The GALR2 antagonist M871 injected alone in the dose of 3nmol lacked effects on immobility time (141 ± 12 sec) and swimming time (68.7 ± 10 sec) in the FST.

2. Effects of siRNA GALR2 knockdown

Then, we used knockdown GALR2 rats to establish the involvement of the GALR2 in the interaction between GAL(1-15)(1nmol) and FLX(10mg/kg) (Figure 2B).

The one-way ANOVA revealed a significant effects of the treatment used in the immobility ($F_{2,17}=5.932$, $p<0.05$) and swimming behaviours ($F_{2,17}=5.932$, $p<0.01$). The three sc injections of FLX(10mg/kg) produced antidepressant-like effects in the siRNA GALR2 knockdown animals with a decrease in the immobility time (Figure 2B; post hoc $p<0.05$) and an increase in the swimming time (Figure 2B; post hoc $p<0.01$) compared to a control group of siRNA GALR2 knockdown rats. Moreover, the coadministration of the three sc injections of FLX(10mg/kg) and a single icv injection of GAL(1-15) in siRNA GALR2 knockdown animals did not produce a further reduction of the immobility time and a further increase in the swimming time compared to FLX alone (Figure 2B). GAL(1-15)(1nmol) injected alone lacked effects in the FST in knockdown GALR2 animals compared to control group in terms of immobility (14.7 ± 3 s), swimming (81.7 ± 3 s) and climbing times (60 ± 4 s).

3. Effects of siRNA GALR1 knockdown

An siRNA GALR1 knockdown in rats was used to determine the involvement of the GALR1 in the effect induced by GAL(1-15) on FLX in the FST. In this model, previously used in our laboratory, it was possible to validate a reduction by 30% of the expression of GALR1 by immunochemical assay in the CA1 area of the dorsal hippocampus (Figure 3C; $t_{14}=2.317$, $p<0.05$) and DG (Figure 3C; $t_{14}=2.359$, $p<0.05$).

In the FST on the siRNA GALR1 knockdown rats, the three sc injections of FLX(10mg/Kg) produced antidepressant-like effects with a decrease in the immobility time (Figure 3A; $t_{16}=2,778$, $p<0,05$) and an increase in the swimming time (Figure 3A; $t_{16}=2,041$, $p<0.05$) compared to the control group of GALR1 knockdown rats. Moreover, in a different set of experiments, the coadministration of the three sc injections of FLX(10mg/Kg) and a single icv injection of GAL(1-15)(1nmol) in GALR1 knockdown animals did not produce a statistically significant difference compared to FLX(10mg/kg) group alone in the immobility time (Figure 3B; $t_{15}=0.121$) nor in the swimming time (Figure 3B; $t_{14}=0.319$).

5HT1AR is involved in the GAL (1-15)–FLX interaction

To determine the role of 5HT1AR in the behavioral interaction between GAL(1-15) and FLX the 5HT1AR antagonist WAY100635 was used (Figure 4).

The results confirmed that the 5HT1AR participates in this interaction as the 5HT1AR antagonist WAY100635 (6nmol) significantly blocked the reduction in immobility time ($F_{3,30}=4.243$, $p<0.05$;post hoc, $p<0.05$), and the increase in swimming time ($F_{3,29}=16.83$, $p<0.001$;post hoc, $p<0.01$) induced by the coadministration of icv GAL(1-15) and the three injections of sc FLX(10mg/kg) in the FST (Figure 4).

The 5HT1AR antagonist WAY100635 (6nmol) injected alone significantly increased the immobility time (101 ± 12 sec) ($t_{13}=2,617$, $p<0,01$) and lacked effect in swimming time (87 ± 6 sec) ($t_{13}=0,2135$, $p=0.4172$) in the FST. However, the coadministration of three sc injections of FLX and a single icv

injection of WAY100635 (6nmol) did not produce any difference compared with the effect of FLX alone (Figure 4).

Neurochemical effects

GAL(1–15)+FLX modify the mRNA levels and the binding characteristics of 5-HT1AR in the dorsal hippocampus.

1. 5-HT1A mRNA levels

The coadministration of the three sc injections of FLX(10mg/Kg) and a single icv injection of GAL(1-15)(1nmol) produced a significant increase in the 5HT1AR mRNA levels in CA1 (Figure 5; $F_{3,18}=8.803$, $p<0.001$; post hoc, $p<0.05$) and DG (Figure 4; $F_{3,17}=5.033$, $p<0.05$; post hoc, $p<0.05$) of the dorsal hippocampus compared to controls and single treatments. This effect was not observed in the DR (Table S2; $F_{3,19}=0.983$; $p=0.422$).

Representative autoradiograms illustrate the increase of 5HT1AR mRNA levels in both areas, CA1 and DG, after the coadministration of the three sc injections of FLX (10mg/Kg) and the single icv injection of GAL(1-15)(1nmol) (Figure 5B).

2. 5-HT1A agonist radioligand binding. Saturation curves

In the autoradiographic experiments, the coadministration of the three injections of sc FLX (10mg/Kg) and a single icv injection of GAL(1-15)(1nmol) produced a significant decrease in the K_d value (Figure 6; $t_9=2.916$, $p<0.01$) and in the B_{max} value (Figure 6; $t_9=2.277$, $p<0.05$) of the agonist radioligand [3 H]-8-OH-DPAT in the DG of the dorsal Hippocampus compared to FLX(10mg/Kg) alone. Representative autoradiograms with a low radioligand concentration (1nM) illustrate the increase of labelling (decrease in K_d values) in the DG 30 minutes after the coadministration of the three injections of sc FLX (10mg/Kg) and the single icv injection of GAL1-15 (1nmol) (Figure 6B).

These effects were not observed in the CA1 area of the Hippocampus neither in the B_{max} (Table S3; $t_9=0,9420$, $p=0,1854$) nor in the K_d values (Table S3; $t_9=0,01385$, $p=0,4946$) neither in the DR in the B_{max} (Table S3; $t_9=0,8648$,

$p=0,2048$) or in the K_d (Table S3; $t_9=0,9941$, $p=0,173$).

DISCUSSION

In the current study we describe for the first time that GAL(1-15) enhances the antidepressant-like effects induced by FLX in the FST. These effects were specific since GAL lacks effect. Indications were also obtained for the involvement of a GALR1/GALR2 heteroreceptor complex in the GAL (1-15)-mediated actions based on the use of the specific GALR2 antagonist M871 and icv injections of GALR1 siRNA or GALR2 siRNA producing a reduction of GALR1 or GALR2, respectively.

Importantly, 5HT1AR participates in the GAL(1-15)/FLX interactions since the 5HT1AR antagonist WAY100635 blocked the behavioral effects in the FST induced by the coadministration of GAL(1-15) and FLX. The mechanism underlying the GAL(1-15)/FLX interactions involved increases in the affinity of 5HT1AR agonist binding in the DG with changes also at the transcriptional level in both CA1 and DG. GAL(1-15)/FLX interactions affected the binding characteristics as well as the mRNA levels of 5-HT1AR specifically in the dorsal hippocampus while leaving the 5-HT1A mRNA levels receptor agonist binding unaffected in the dorsal raphe.

The FST is used as a behavioral test to predict the efficacy of antidepressant treatments. The FST is an attractive behavioral screen for antidepressant drugs since it is quick to perform, reliable across laboratories, and sensitive to the effects of all of the major classes of antidepressant drugs. In this test the main indication of an antidepressant-like action of any given compound is a decrease in immobility behavior (Detke et al., 1995a; Detke et al., 1995b). The scoring of the active behaviors swimming and climbing give additional information about the mechanism of action that mediates the antidepressant-like effect. In fact, selective 5-HT reuptake inhibitors decrease immobility and increase swimming behavior (Detke et al., 1995a; Detke et al., 1995b).

In the current study FLX 10 mg/kg injected -23, -5 and -1 h before the 5 min test significantly reduced the immobility and increased swimming time in the FST.

These results obtained agree with previous studies and validates the behavioral model used (Estrada-Camarena et al., 2006). Moreover, FLX at 2.5mg/kg lacks effects, results which are again in agreement with those of other authors (Detke et al., 1997).

In the current work we demonstrated that GAL(1-15) enhanced FLX induced antidepressant effects in the FST. A decrease in immobility behavior and an increase of swimming behavior were observed following cotreatment with threshold doses of GAL(1-15) and of FLX (2.5 mg/kg). When administered alone, neither GAL(1-15) 1 nmol nor 2.5 mg/kg of FLX affected the performance in the test, indicating that GAL(1-15) and FLX interact to provoke the enhanced antidepressant like responses. Since GAL(1-15) at an effective dose induced a pro-depressive effect (Millon et al., 2015), the antidepressant effect could only be due to the enhancement of FLX action. Moreover, the strong enhancement by GAL(1-15) of the antidepressant FLX action was validated using an effective dose of FLX.

It was demonstrated that GAL(1-15) involves GALR1-GALR2 interactions to enhance the antidepressant effects of FLX in the FST. GALR2 is involved in the GAL(1-15) effects since the GALR2 antagonist M871 blocked the enhancement of the FLX antidepressant effects induced by GAL(1-15). We were also able to block the ability of GAL(1-15) to enhance the FLX induced behavioral effects through use of rats with in vivo siRNA induced GALR1 or GALR2 knockdown, validating the concept that GAL(1-15) actions depend on the existence of GALR1-GALR2 heteroreceptor complexes in the brain.

Moreover in siRNA GALR1 and GALR2 knockdown rats, FLX alone reduced the immobility and increased swimming time in the FST, showing that the effect of FLX is not affected by the reduction of GALR1 or GALR2 expression.

We have previously described that GAL(1-15) alone acts through GALR1-GALR2 heteroreceptor complexes which preferentially bind GAL(1-15) (Borrito-Escuela et al., 2014; Fuxe et al., 2012; Millon et al., 2016; Millon et al., 2015) and these heteroreceptor complexes were observed in the nerve cells of the dorsal hippocampus and DR (Millon et al., 2015). The results in the current paper validate that the effects of GAL(1-15) through GALR1-GALR2

heteroreceptor complexes could be a key mechanism in depression. Furthermore, the enhancing effects of GAL(1–15) on FLX mediated actions in the FST were specific, since no effects were induced by GAL, which validates and extends the view of a specific role of GAL(1–15) in brain communication.

The fact that the enhancement of the antidepressant action of FLX by GAL(1–15) was blocked by the 5-HT_{1A}R antagonist WAY100635 indicates that the 5-HT_{1A}R has a significant participation in this interaction. Several authors have reported that WAY100635 when administered together with an effective dose of FLX, cancels the action of this SSRI (Estrada-Camarena et al., 2006; Serres et al., 2000). However, if the antagonist is administered in a different time point, like in the current study, the antidepressant-like activity of FLX in the FST is maintained (Estrada-Camarena et al., 2006; Serres et al., 2000). This observation of a time-schedule of injection in which WAY100635 could not prevent the antidepressant-like activity of FLX alone in the FST is of high interest. It supports the notion that GAL(1–15) through agonist activation of allosteric GALR1-GALR2-5-HT_{1A} receptor-receptor interactions in putative trimeric heteroreceptor complexes may include effects on the recognition, pharmacology and signaling of the participating 5-HT_{1A}R protomers. Such events can facilitate the understanding of the mechanism for the enhancement of the antidepressant actions of FLX by GAL(1–15).

We have previously described that GAL(1–15) alone acts through GALR1-GALR2 isoreceptor complexes (Fuxe et al. 2012; Fuxe et al. 2008; Millon et al. 2015; Borroto-Escuela et al. 2014). These complexes could operate via allosteric GALR1-GALR2 interactions that inhibit the Gq/G11-mediated signaling of the GALR2 protomer and switches the isoreceptor complex towards Gi/o-mediated signaling (Borroto-Escuela et al. 2014; Millon et al. 2015).

The FLX induced increases in extracellular levels of 5-HT may also favor the formation of putative higher order GALR1-GALR2-5-HT_{1A} heteroreceptor complexes. In such a complex altered allosteric receptor-receptor interactions can develop with an ability of the GALR1-GALR2

component to enhance the 5-HT_{1A} protomer signalling. This possibility remains to be tested.

Because not only 5-HT_{1AR}, but also 5-HT₄, 5-HT_{2A}, 5-HT₃ and 5-HT₇ receptors are involved in modulating the effects of antidepressant treatments, the participation of other 5-HT receptor subtypes in the interaction should also be analyzed.

We have recently described that GAL(1–15) enhanced the antidepressant effects induced by the 5-HT_{1AR} agonist 8-OH-DPAT in the FST (Millon et al., 2016). Thus, a significant decrease in the immobility and an increase in climbing behavior appeared after the coadministration of GAL(1-15) and 8-OH-DPAT and an increase of the swimming behavior versus the 8-OH-DPAT alone group was also observed (Millon et al., 2016). **These antidepressant effects were independent of the locomotor activity, as the total distances reached and speed were equivalent between all the group** (Millon et al., 2016). In the current work FLX, as a selective serotonin reuptake inhibitor binds to the serotonin transporter (SERT), thereby blocking 5-HT uptake and enhancing 5-HT volume transmission through decreasing the clearance of extracellular 5-HT levels (Fuxe et al., 2010).

This increase in extracellular levels of 5-HT leads to an activation of a panorama of 5-HT receptor subtypes including 5-HT_{1A} homo and heteroreceptor complexes. We do not know which are the major types of 5-HT homo and heteroreceptor complexes involved in the antidepressant effects of FLX but the putative 5-HT_{1AR}-GALR1-GALR2 heteroreceptor complexes are likely one relevant target for the mediation of the enhancement by GAL(1-15) of the antidepressant actions of FLX.

In previous work it was found that GAL(1-15) affected the binding characteristics as well as the mRNA levels of 5-HT_{1AR} in the dorsal hippocampus and DR (Millon et al., 2016). In this work we observed a modification in the binding characteristics and also in the mRNA levels of 5-HT_{1AR} after coadministration of FLX and GAL(1-15). In fact, the coadministration of GAL(1-15) and FLX induced an increase in the mRNA levels of postjunctional 5-HT_{1AR} in the dorsal hippocampus and a decrease in K_d and

Bmax values, specifically in the DG of the hippocampus. These results indicate an important role of postjunctional hippocampal 5-HT_{1A}R and their expression in the GAL(1-15)-FLX interaction. Thus, no effects were observed in the DR on the binding characteristics of soma-dendritic 5-HT_{1A} autoreceptors nor on their expression.

In previous work, we observed that 10 minutes after icv GAL(1-15) administration, no effect was observed in the 5HT-1A receptors in the DR (Millon et al., 2016). Our results suggest that in the short term, the DR is not the key nucleus in the antidepressant effects induced by GAL(1-15). However we cannot exclude that a potential enhancement in the firing rate of the ascending 5-HT DR neurons was induced by GAL(1-15) by counteracting the 5-HT induced autoreceptor signaling in spite of lack of effects on 5-HT_{1A} autoreceptor recognition.

In conclusion, our results indicate that icv GAL (1-15) enhances the antidepressant effects induced by FLX in the FST. The target for GAL(1-15) may mainly be 5-HT_{1A}R-GALR1-GALR2 heteroreceptor complexes and their allosteric receptor-receptor interactions located postjunctionally in the dorsal hippocampus (Fuxe et al., 2012; Fuxe et al., 2008; Millon et al., 2016; Millon et al., 2015). In contrast, GAL appears to mainly target GALR1-5-HT_{1A} and GALR2-5-HT_{1A} heteroreceptor complexes (Borroto-Escuela et al., 2010; Millon et al., 2016; Millon et al., 2015). The results open up the possibility to use intranasal GAL(1-15) as a combination therapy with FLX as a novel strategy for treatment of depression.

Figure legends

Figure 1. Behavioural effects of the coadministration of effective dose of FLX (10mg/Kg) and GAL(1-15) (1nmol) or Galanin (1nmol) in the FST. FLX was administered subcutaneously (sc) 23, 5 and 1 hour before the test. CSFa,

GAL(1-15) and Galanin were injected intracerebroventricular (icv) 15 min before the test. Data represents mean \pm SEM of immobility, climbing and swimming time in FST during the 5 min test period (n=7-8 rats per group). * p <0.05, ** p <0.01 versus all the groups; # p <0.05 versus Control according to one way ANOVA followed by Newman-Keuls Multiple Comparison Test.

Figure 2. Behavioural effects of the coadministration of effective dose of FLX (10mg/Kg) and threshold doses of GAL(1-15) (1nmol) in (A) Sprague-Dawley rats which also were treated with GALR2 antagonist M871 (3nmol) or (B) GALR2 knockdown rats (siRNA GALR2). FLX or vehicle was administered subcutaneously (sc) 23, 5 and 1 hour before the test. aCSF, GAL(1-15) and GAL(1-15)+M871 were injected intracerebroventricularly (icv) 15 min before the test. Data represents mean \pm SEM of immobility, climbing and swimming times in FST during the 5 min test period (n=7-9 rats per group). # p <0.05, ## p <0.01 versus FLX10mg(sc)+CSFa(icv) and FLX10mg(sc)+GAL(1-15) 1nmol+M871 3nmol (icv); * p <0.05, ** p <0.01 versus Control according to one way ANOVA followed by Newman-Keuls Multiple Comparison Test.

Figure 3. Behavioural effects of effective dose of FLX 10mg/Kg (A) and coadministration of FLX 10mg/Kg and threshold doses of GAL(1-15)(1nmol) (B) in GALR1 knockdown rats (siGalR1). FLX and vehicle was administered sc 23, 5 and 1 hour before the test. CSFa, GAL(1-15) were injected icv 15 min before the test. Data represents mean \pm SEM of immobility, climbing and swimming time in FST during the 5 min test period (n=7-9 rats per group) * p <0.05 according to Student's unpaired t-test. (C) GALR1 protein expression eight days after a single i.c.v. injection of siRNA GALR1 or vehicle into the rat brain. Data are represents as mean \pm SEM of the percentages respect the control value (100%) of optic density (O.D) * p <0.05 according to Student's unpaired t-test. (D) Representative photographs of GALR1 immunohistochemistry

Figure 4. Behavioural effects of the coadministration of effective dose of FLX (10mg/Kg) and 5-HT1A antagonist WAY100635 (6nmol) and the coadministration of effective dose of FLX (10mg/Kg) with GAL(1-15) (1nmol)

and WAY100635 (6nmol) in the FST. FLX was administered sc 23, 5 and 1 hour before the test. GAL(1-15), WAY100635 and GAL(1-15)+WAY100635 were injected icv 15 min before the test. Data represents mean \pm SEM of immobility, climbing and swimming times in FST during the 5 min test period (n=5-10 rats per group). *p<0.05, **p<0.01 versus all groups according to one-way ANOVA followed by Newman-Keuls Multiple Comparison Test.

Figure 5. (A) Effects of the coadministration of FLX (10mg/Kg) and GAL(1-15) (1nmol) on 5-HT_{1A}R mRNA levels in dorsal hippocampus (CA1 and DG). FLX was administered sc 23, 5 and 1,25 hour before sacrifice and GAL(1-15) was injected icv 30 min before sacrifice. The values of optical density (O.D.), mean \pm SEM (n=6 per group), are expressed as percentages respect of the control values (100%). *p<0.05 versus all groups according to one way ANOVA followed by Newman-Keuls Multiple Comparison Test (B) Representative autoradiograms from dorsal hippocampus showing the levels of mRNA coding for 5-HT_{1A}R determined by *in situ* hybridization and the analyzed areas.

Figure 6. Effects on the binding characteristics of 5-HT_{1A}R agonist [³H]-8-OH-DPAT in the dental gyrus (DG) of the hippocampus (A) after the coadministration of FLX (10mg/Kg) and aCSF or GAL(1-15) (1nmol). FLX was administered sc 23, 5 and 1,25 hour before sacrifice and GAL(1-15) or CSFa was injected icv 30 min before. Saturation experiments were performed with ten concentrations of [³H]-8-OH-DPAT (0.26-10nM) in sections from the Hippocampus. Non-specific binding was defined as the binding in the presence of 10 μ M serotonin. The K_d and the B_{max} values are shown as mean \pm SEM (n=6 per group). In FLX(10mg/kg) the K_d (nM) value was 1.2 \pm 0.1 and B_{max} (fmol/mg prot) was 545 \pm 37. *p<0.05; **p<0.01 according to Student's unpaired t-test. (B) Representative autoradiograms from Hippocampus sections of rat showing an increase of the affinity of the agonist for 5-HT_{1A}R with a low concentration of the radioligand (1 nM).
